

Ella's Water Intake

and how her life
effects it

Goal: to understand how the **duration of my work shifts (hours)** influences **my water intake (liters)**.

I collected data for **39** days from April 27, 2026 to May 25, 2026.

to do list

☐ Shift length (hrs)

☐ Daily steps

☐ Temperature
(h/w/c)

☐ Sickness (y/n)

☐ Work/School (y/n)

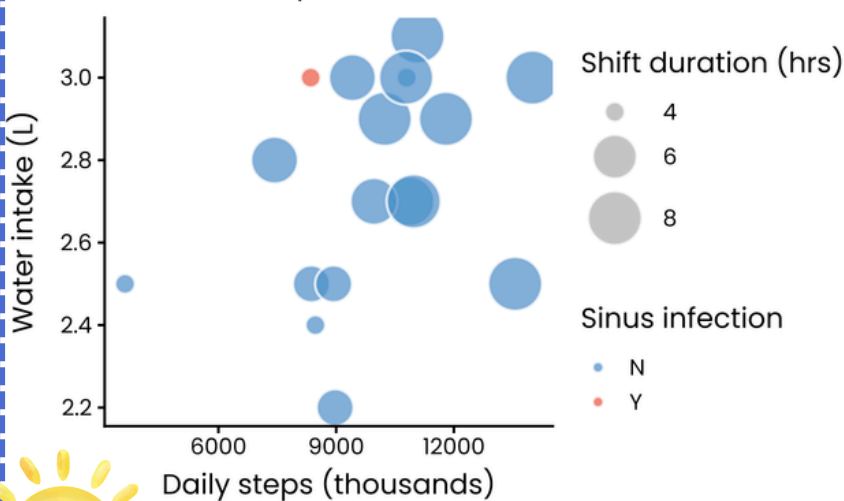

I recorded lots of variables: all things that influence my daily water intake. These indicate the **movement**, **busyness**, and **flow** of my day.

The **longer shifts** I completed, the **more steps** I took, and the **more water** I drank.

Other variables also had great impacts!

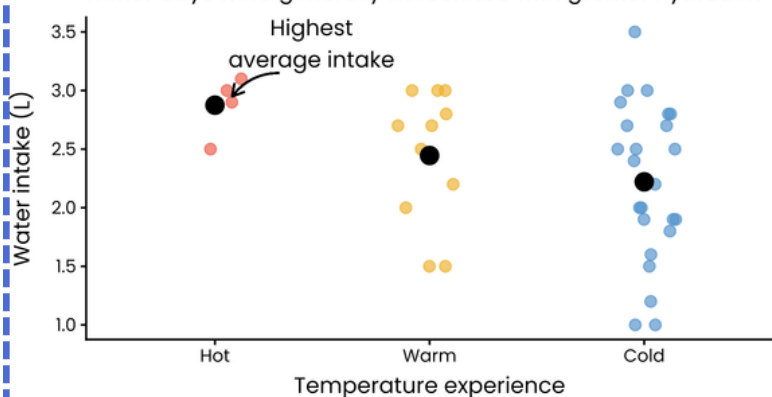

More demanding days required more hydration
Bubble size represents work shift duration

There was also a consistent relationship found with temperature: the **warmer** I felt, the **more** I drank.

Water intake varied with temperature experience
Hotter days were generally associated with greater hydration

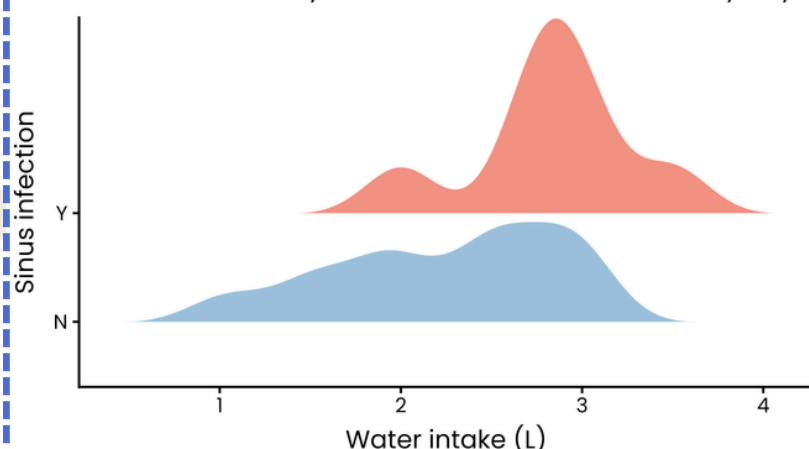

I spent **32 days** not sick & **7 days** sick ... which greatly influenced my water intake!

82%
Not sick

18%
Sick

Hydration patterns shifted during illness
Distribution of daily water intake on sick and healthy days

Every variable I measured contributed to how much water I consumed, showing that it is a **product of the conditions** I experience daily!
